From set theory to universal algebra

- ▶ classical set theory (for example, Zermelo–Fraenkel):
 - ▶ sets
 - ▶ functions from sets to sets
 - ▶ composition of functions yields function
 - ▶ identity functions exist
- ▶ adding structure and preserving it:
 - ▶ vector spaces
 - ▶ linear maps from vector spaces to vector spaces
 - ▶ composition of linear maps yields linear map
 - ▶ identity functions are linear maps
- ▶ generalization of this idea in universal algebra:
 - ▶ certain algebras with the same signature
 - ▶ homomorphisms from such algebras to other such algebras
 - ▶ composition of homomorphisms yields homomorphism
 - ▶ identity functions are homomorphisms

Beyond universal algebra

- ▶ topology based on the Kuratowski axioms:
 - ▶ topological space is a set X and a closure operator

$$\text{cl} : \mathcal{P}(X) \rightarrow \mathcal{P}(X)$$

that fulfills certain axioms

- ▶ continuous function from (X, cl) to (X', cl')
is a function $f : X \rightarrow X'$ with

$$f(\text{cl}(A)) \subseteq \text{cl}'(f(A))$$

- ▶ does not fit into the universal algebra framework:
 - ▶ closure operator operates on sets
instead of single elements
 - ▶ continuity axiom uses \subseteq instead of $=$
- ▶ will fit into the categorical framework

No elements anymore

- ▶ revision control system darcs:
 - ▶ repository states
 - ▶ patches that turn repository states into repository states
 - ▶ composition of patches yields patch
 - ▶ empty patches exist
- ▶ repository states do not have elements
- ▶ will fit into the categorical framework nevertheless
- ▶ more about a categorical approach to darcs in [Swierstra]

Categories

- ▶ components of a category:
 - ▶ a class of objects
 - ▶ class of morphisms, each having a unique domain and a unique codomain, which are objects
 - ▶ composition of morphisms:

$$\frac{f : A \rightarrow B \quad g : B \rightarrow C}{gf : A \rightarrow C}$$

- ▶ identity morphisms:
$$\text{id}_A : A \rightarrow A$$
- ▶ axioms that have to hold:
 - ▶ composition is associative
 - ▶ id is left and right unit
- ▶ classes of objects and morphism are not necessarily sets:
 - allows categories of sets, vector spaces, etc.
- ▶ composition is partial:
 - codomain and domain must match
- ▶ above constructions lead to categories **Set**, **Vec**, etc.

- ▶ axioms still hold after doing the following:
 - ▶ swapping domain and codomain of each morphism
 - ▶ changing the argument order of composition
- ▶ opposite category \mathcal{C}^{op} for every category \mathcal{C} :
 - ▶ objects of \mathcal{C}^{op} are the ones of \mathcal{C}
 - ▶ morphisms $f : A \rightarrow B$ of \mathcal{C}^{op} are the morphism $f : B \rightarrow A$ of \mathcal{C}
 - ▶ compositions gf in \mathcal{C}^{op} are the compositions fg in \mathcal{C}
 - ▶ identities in \mathcal{C}^{op} are the same as in \mathcal{C}
- ▶ consequences:
 - ▶ for every categorical notion N , there is a dual notion N^{op} such that something is an N^{op} in \mathcal{C} if it is an N in \mathcal{C}^{op}
 - ▶ for every theorem, there is a dual theorem that refers to the dual notions

Products of categories

- ▶ product category $\mathcal{C} \times \mathcal{D}$ for any two categories \mathcal{C} and \mathcal{D} :

- ▶ objects

$$(A, B)$$

where A is an object of \mathcal{C} , and B is an object of \mathcal{D}

- ▶ morphisms

$$(f, g) : (A, B) \rightarrow (A', B')$$

where $f : A \rightarrow A'$ and $g : B \rightarrow B'$

- ▶ compositions and identities defined componentwise:

$$(f', g')(f, g) = (f'f, g'g)$$

$$\text{id}_{(A, B)} = (\text{id}_A, \text{id}_B)$$

- ▶ neutral element is the category $\mathbf{1}$:

- ▶ exactly one object
- ▶ exactly one morphism (the identity of that object)

Categories and elements

- ▶ in general, no notion of element of an object
- ▶ however, elements can be recovered for specific kinds of categories
- ▶ furthermore, some concepts that seem to require the notion of element actually do not

Injectivity

Definition (Injectivity)

A function $f : A \rightarrow B$ is injective if and only if

$$\forall x_1, x_2 \in A . f(x_1) = f(x_2) \Rightarrow x_1 = x_2 \quad .$$

Theorem

A function $f : A \rightarrow B$ is injective if and only if

$$\forall C . \forall g_1, g_2 : C \rightarrow A . fg_1 = fg_2 \Rightarrow g_1 = g_2 \quad .$$

- ▶ above definition relies on the notion of element
- ▶ theorem gives us another property for defining injectivity:
 - ▶ does not mention elements, but only sets and functions (point-free style)
 - ▶ can therefore be generalized to arbitrary categories
 - ▶ leads to the notion of monomorphism

Surjectivity

Definition (Surjectivity)

A function $f : A \rightarrow B$ is surjective if and only if

$$\forall y \in B . \exists x \in A . f(x) = y \quad .$$

Theorem

A function $f : A \rightarrow B$ is surjective if and only if

$$\forall C . \forall g_1, g_2 : B \rightarrow C . g_1 f = g_2 f \Rightarrow g_1 = g_2 \quad .$$

- ▶ theorem gives us point-free definition
- ▶ generalization to arbitrary categories leads to the notion of epimorphism
- ▶ point-free style makes it clear that monomorphism and epimorphism (injectivity and surjectivity) are duals

Isomorphisms

- ▶ generalization of bijections
- ▶ morphism $f : A \rightarrow B$ is an isomorphism if there is an $f^{-1} : B \rightarrow A$ such that

$$f^{-1}f = \text{id}_A \qquad ff^{-1} = \text{id}_B$$

- ▶ objects A and B are isomorphic ($A \cong B$) if there exists an isomorphism $f : A \rightarrow B$

References

Cartesian products

- ▶ pair construction:

$$\frac{x \in A \quad y \in B}{(x, y) \in A \times B}$$

- ▶ pair destruction:

$$\pi_1 : A \times B \rightarrow A \quad \pi_2 : A \times B \rightarrow B$$

- ▶ destruction is point-free, construction is not
- ▶ construction can be made point-free:

$$\frac{f : C \rightarrow A \quad g : C \rightarrow B}{\langle f, g \rangle : C \rightarrow A \times B}$$

where

$$\forall z \in C . \langle f, g \rangle(z) = (f(z), g(z))$$

Products

- ▶ generalization of cartesian products
- ▶ a product of A and B is an object $A \times B$ together with morphisms

$$\pi_1 : A \times B \rightarrow A \qquad \pi_2 : A \times B \rightarrow B$$

(called projections) for which the following holds:

- ▶ for every object C , we have

$$\frac{f : C \rightarrow A \quad g : C \rightarrow B}{\langle f, g \rangle : C \rightarrow A \times B}$$

- ▶ the following holds:

$$\pi_1 \langle f, g \rangle = f \qquad \pi_2 \langle f, g \rangle = g$$

- ▶ the morphism $\langle f, g \rangle$ is unique
- ▶ two objects A and B may not have a product
- ▶ products of two specific objects are unique up to isomorphism

Coproducts

- ▶ duals of products
- ▶ a coproduct of A and B is an object $A + B$ together with morphisms

$$\iota_1 : A \rightarrow A + B \qquad \iota_2 : B \rightarrow A + B$$

(called injections) for which the following holds:

- ▶ for every object C , we have

$$\frac{f : A \rightarrow C \quad g : B \rightarrow C}{[f, g] : A + B \rightarrow C}$$

- ▶ the following holds:

$$[f, g]\iota_1 = f \qquad [f, g]\iota_2 = g$$

- ▶ the morphism $[f, g]$ is unique
- ▶ two objects A and B may not have a coproduct
- ▶ coproducts of two specific objects are unique up to isomorphism

Terminal and initial objects

- ▶ nullary versions of products and coproducts
- ▶ 1 is a terminal object if there is a unique morphism

$$! : C \rightarrow 1$$

for every object C

- ▶ 0 is an initial object if there is a unique morphism

$$? : 0 \rightarrow C$$

for every object C

- ▶ terminal and initial objects are unique up to isomorphism
- ▶ if terminal object exists, $A \times 1$ and $1 \times A$ exist for every object A , and we have

$$A \times 1 \cong A \cong 1 \times A$$

- ▶ analogously for initial object

Function spaces

- ▶ for sets A and B , we have

$$B^A = \{f \mid f : A \rightarrow B\}$$

- ▶ Currying:

$$\frac{f : C \times A \rightarrow B}{\lambda_f : C \rightarrow B^A}$$

- ▶ function application:

$$\epsilon : B^A \times A \rightarrow B$$

where

$$\epsilon(f, x) = f(x)$$

Exponentials

- ▶ generalization of function spaces
- ▶ defined for categories where all (binary) products exist
- ▶ an exponential of A and B is an object B^A together with a morphism

$$\epsilon : B^A \times A \rightarrow B$$

for which the following holds:

- ▶ for every object C , we have

$$\frac{f : C \times A \rightarrow B}{\lambda_f : C \rightarrow B^A}$$

- ▶ the following holds:

$$\epsilon \langle \lambda_f \pi_1, \pi_2 \rangle = f$$

- ▶ the morphism λ_f is unique
- ▶ two objects A and B may not have an exponential
- ▶ exponentials of two specific objects are unique up to isomorphism

Cartesian closed categories and beyond

Definition (Cartesian closed category)

A category is a cartesian closed category (CCC) if it has all (binary) products, a terminal object, and all exponentials.

Definition (Bicartesian closed category)

A category is a bicartesian closed category (BCCC), sometimes called cocartesian closed category (CCCC), if it is a CCC and has all (binary) coproducts and an initial object.

Categorical logic basics

- ▶ categories as models of logics
- ▶ general idea:
 - ▶ objects model propositions
 - ▶ if objects A and B model propositions φ and ψ , morphisms $f : A \rightarrow B$ model proofs of $\varphi \vdash \psi$
 - ▶ composition models composition of proofs:

$$\frac{\varphi \vdash \psi \quad \psi \vdash \chi}{\varphi \vdash \chi}$$

- ▶ identities model identity rule:

$$\frac{}{\varphi \vdash \varphi}$$

- ▶ BCCCs are the models of intuitionistic propositional logic
- ▶ for modeling other intuitionistic logics, extend BCCCs with additional structure
- ▶ even linear logic can be modeled by extended BCCCs

Products and conjunctions

- ▶ \times models \wedge :

- ▶ $\langle \cdot, \cdot \rangle$ proves conjunction introduction:

$$\frac{\chi \vdash \varphi \quad \chi \vdash \psi}{\chi \vdash \varphi \wedge \psi}$$

- ▶ projections prove conjunction elimination:

$$\frac{}{\varphi \wedge \psi \vdash \varphi} \qquad \frac{}{\varphi \wedge \psi \vdash \psi}$$

- ▶ 1 models \top :

- ▶ $!$ proves truth:

$$\frac{}{\chi \vdash \top}$$

Coproducts and disjunctions

- ▶ + models \vee :

- ▶ $[\cdot, \cdot]$ proves disjunction elimination:

$$\frac{\varphi \vdash \chi \quad \psi \vdash \chi}{\varphi \vee \psi \vdash \chi}$$

- ▶ injections prove disjunction introduction:

$$\overline{\varphi \vdash \varphi \vee \psi}$$

$$\overline{\psi \vdash \varphi \vee \psi}$$

- ▶ 0 models \perp :

- ▶ ? proves *ex falso quodlibet*:

$$\overline{\perp \vdash \chi}$$

Exponentials and implications

- ▶ exponentiation models \Rightarrow :

- ▶ λ proves implication introduction:

$$\frac{\chi \wedge \varphi \vdash \psi}{\chi \vdash \varphi \Rightarrow \psi}$$

- ▶ ϵ proves implication elimination:

$$\overline{(\varphi \Rightarrow \psi) \wedge \varphi \vdash \psi}$$

Functors

- ▶ structure-preserving maps between categories (“category homomorphisms”)
- ▶ functor $F : \mathcal{C} \rightarrow \mathcal{D}$ actually consists of two maps:
 - ▶ a map from objects of \mathcal{C} to objects of \mathcal{D}
 - ▶ a map from morphisms of \mathcal{C} to morphisms of \mathcal{D}
- ▶ notation for application of these maps uses juxtaposition of functor and argument:
 - ▶ application of F 's object map to object A is FA
 - ▶ application of F 's morphism map to morphism f is Ff
- ▶ axioms:
 - ▶ transformation of domains and codomains:

$$\frac{f : A \rightarrow B}{Ff : FA \rightarrow FB}$$

- ▶ compatibility with composition:

$$F(gf) = (Fg)(Ff)$$

- ▶ compatibility with identities:

$$Fid_A = id_{FA}$$

Functor examples

- ▶ power set functor from **Set** to itself:
 - ▶ object map turns sets into their power sets:

$$\mathcal{P}A = \{M \mid M \subseteq A\}$$

- ▶ morphism map turns functions into elementwise applications of them:

$$(\mathcal{P}f)(M) = \{f(x) \mid x \in M\}$$

- ▶ list functor from functional programming is similar:
 - ▶ object map turns element types into list types
 - ▶ morphism map turns functions into elementwise applications of them
- ▶ projections of product categories:
 - ▶ object maps turn pairs of objects into objects:

$$\Pi_1(A, B) = A \qquad \Pi_2(A, B) = B$$

- ▶ morphism maps turn pairs of morphisms into morphisms:

$$\Pi_1(f, g) = f \qquad \Pi_2(f, g) = g$$

Functor intuitions

- ▶ container intuition:
 - ▶ object map turns types/sets of elements into types/sets of containers
 - ▶ morphism map turns functions into elementwise applications of them
- ▶ effect intuition:
 - ▶ object map turns types/sets of results into types/sets of effectful computations
 - ▶ morphism map turns functions into functions that append the former functions to effectful computations
- ▶ application to power set functor:
 - ▶ sets are containers
 - ▶ sets denote nondeterministic computations

Category of small categories

- ▶ composition $GF : \mathcal{C} \rightarrow \mathcal{E}$ of functors $F : \mathcal{C} \rightarrow \mathcal{D}$ and $G : \mathcal{D} \rightarrow \mathcal{E}$:
 - ▶ object map is composition of object maps of F and G
 - ▶ morphism map is composition of morphism maps of F and G
- ▶ identity functor $\text{Id} : \mathcal{C} \rightarrow \mathcal{C}$:
 - ▶ object map is identity function on objects
 - ▶ morphism map is identity function on morphism
- ▶ category **Cat** of categories and functors:
 - ▶ objects are all categories
 - ▶ morphisms $F : \mathcal{C} \rightarrow \mathcal{D}$ are the functors $F : \mathcal{C} \rightarrow \mathcal{D}$
 - ▶ composition is functor composition
 - ▶ identities are the identity functors
- ▶ set theory in use might not allow for the class of all categories
- ▶ objects of **Cat** are only all small categories:
 - ▶ object classes are sets
 - ▶ morphism classes are sets

Natural transformations

- ▶ natural transformation τ from functor F to functor G is an indexed family of morphisms

$$\tau_A : FA \rightarrow GA ,$$

one for each object A

- ▶ compatibility with morphism maps:

$$\tau_B(Ff) = (Gf)\tau_A$$

Functor categories

- ▶ important properties of natural transformations:
 - ▶ pointwise composition yields natural transformation
 - ▶ pointwise identities are natural transformations
- ▶ functor category:
 - ▶ objects are all functors from a certain source to a certain target category
 - ▶ morphisms $\tau : F \rightarrow G$ are the natural transformations from F to G
 - ▶ compositions and identities constructed pointwise
- ▶ natural isomorphisms:
 - ▶ are the isomorphisms of functor categories
 - ▶ are exactly those natural transformations that consist only of isomorphisms

Revisiting products and coproducts

► products:

- \times is a functor from $\mathcal{C} \times \mathcal{C}$ to \mathcal{C} with

$$f \times g = \langle f\pi_1, g\pi_2 \rangle$$

- π_1 and π_2 are natural transformations:

$$\pi_1 : \times \rightarrow \Pi_1 \qquad \pi_2 : \times \rightarrow \Pi_2$$

► coproducts:

- $+$ is a functor from $\mathcal{C} \times \mathcal{C}$ to \mathcal{C} with

$$f + g = [\iota_1 f, \iota_2 g]$$

- ι_1 and ι_2 are natural transformations:

$$\iota_1 : \Pi_1 \rightarrow + \qquad \iota_2 : \Pi_2 \rightarrow +$$

Revisiting exponentials

- ▶ exponentiation is a functor $E : \mathcal{C}^{\text{op}} \times \mathcal{C} \rightarrow \mathcal{C}$ with

$$g^f = \lambda_{g \in (\text{id}_{BA} \times f)}$$

- ▶ ϵ is a natural transformation

$$\epsilon : E \times \Pi_1 \rightarrow \Pi_2 ,$$

where $E \times \Pi_1$ is the functor with

$$(E \times \Pi_1)A = EA \times \Pi_1 A$$

and

$$(E \times \Pi_1)f = Ef \times \Pi_1 f$$

categories and
monoidal functors**

Monads and
comonads

References

Monoidal categories

- ▶ categories \mathcal{C} that have the following additional structure:
 - ▶ a functor

$$\otimes : \mathcal{C} \times \mathcal{C} \rightarrow \mathcal{C} ,$$

called the tensor product

- ▶ an object I , called the unit object
- ▶ a natural isomorphism α establishing associativity of \otimes :

$$\alpha_{A,B,C} : (A \otimes B) \otimes C \rightarrow A \otimes (B \otimes C)$$

- ▶ two natural isomorphisms λ and ρ establishing the fact that I is a left and right unit of \otimes :

$$\lambda_A : I \otimes A \rightarrow A \qquad \rho_A : A \otimes I \rightarrow A$$

- ▶ axiom:

For any objects A and B , all morphisms from A to B that are built solely from \otimes , α , λ , and ρ are equal.

- ▶ three dedicated equalities actually enough, since the rest follows from Mac Lane's coherence theorem

Monoidal functors

- ▶ monoidal functor F from monoidal category $(\mathcal{C}, \otimes, I)$ to monoidal category $(\mathcal{C}', \otimes', I')$ consists of the following:
 - ▶ a functor from \mathcal{C} to \mathcal{C}' (also named F)
 - ▶ two natural transformations m and n , called coherence maps:

$$m_{A,B} : FA \otimes' FB \rightarrow F(A \otimes B)$$
$$n : I' \rightarrow FI$$

- ▶ axioms ensure compatibility of coherence maps with α , λ , and ρ
- ▶ F is called strong if coherence maps are isomorphisms
- ▶ comonoidal functor is dual of monoidal functor (coherence maps go into opposite direction)

Monoidal category and functor examples

- ▶ monoidal category examples:
 - ▶ if \mathcal{C} has all finite products, $(\mathcal{C}, \times, 1)$ is a monoidal category
 - ▶ if \mathcal{C} has all finite coproducts, $(\mathcal{C}, +, 0)$ is a monoidal category
- ▶ monoidal functor examples:
 - ▶ list functor is a monoidal functor from $(\mathcal{C}, \times, 1)$ to itself:
 - ▶ m corresponds to *uncurry zip* in Haskell
 - ▶ n corresponds to *repeat* in Haskell
 - ▶ if \mathcal{C} is a category with all finite products and $F : \mathcal{C} \rightarrow \mathcal{C}$, then F is a comonoidal functor from $(\mathcal{C}, \times, 1)$ to itself:

$$m = \langle F\pi_1, F\pi_2 \rangle \qquad n = !_F 1$$

- ▶ infinite list functor is a strong monoidal functor from $(\mathcal{C}, \times, 1)$ to itself:
 - ▶ coherence maps as for lists
 - ▶ inverses of coherence maps are the coherence maps of the abovementioned comonoidal functor

monoidal functors

**Monads and
comonads**

References

- ▶ monad on a category \mathcal{C} consists of the following:

- ▶ a functor $T : \mathcal{C} \rightarrow \mathcal{C}$
- ▶ two natural transformations

$$\eta : \text{Id} \rightarrow T \qquad \mu : TT \rightarrow T$$

- ▶ axioms:

$$\begin{aligned} \mu_A(T\mu_A) &= \mu_A\mu_{TA} : TTTA \rightarrow TA \\ 1_{TA} &= \mu_A(T\eta_A) = \mu_A\eta_{TA} : TA \rightarrow TA \end{aligned}$$

- ▶ consequences:

- ▶ For every n , there are natural transformations from T^n to T that are built solely from T , η , and μ .
- ▶ For every n , all such transformations are equal.

Monad examples

- ▶ power set monad:
 - ▶ μ is general union

$$\bigcup : \mathcal{P}(\mathcal{P}A) \rightarrow \mathcal{P}A$$

- ▶ η is singleton construction

$$\{\cdot\} : A \rightarrow \mathcal{P}A$$

- ▶ list monad:
 - ▶ μ corresponds to *concat* in Haskell
 - ▶ η corresponds to $\lambda x \rightarrow [x]$ in Haskell

Monad intuitions

- ▶ container that can be built from arbitrarily nested containers:
 - ▶ μ turns a two-level nested container into a flat container
 - ▶ η turns a single value (zero-level nested container) into a singleton container
- ▶ effectful computations that can be built from sequences of computations:
 - ▶ μ turns a sequence of two computations into a single computation
 - ▶ η turns a result value into a computation without effect that just returns this value

- ▶ duals of monads
- ▶ comonad on a category \mathcal{C} consists of the following:
 - ▶ a functor $U : \mathcal{C} \rightarrow \mathcal{C}$
 - ▶ two natural transformations

$$\varepsilon : U \rightarrow \text{Id}$$

$$\delta : U \rightarrow UU$$

- ▶ axioms:

$$(U\delta_A)\delta_A = \delta_{UA}\delta_A : UA \rightarrow UUU A$$

$$1_{UA} = (U\varepsilon_A)\delta_A = \varepsilon_{UA}\delta_A : UA \rightarrow UA$$

- ▶ consequences:
 - ▶ For every n , there are natural transformations from U to U^n that are built solely from U , ε , and δ .
 - ▶ For every n , all such transformations are equal.

Comonad example and intuition

- ▶ infinite list comonad as an example:
 - ▶ δ corresponds to *tails* in Haskell
 - ▶ ε corresponds to *head* in Haskell
- ▶ intuition is that of containers that can be turned into arbitrarily nested containers:
 - ▶ δ turns a flat container into a two-level nested container
 - ▶ ε turns a flat container into a single value, which is taken from a special position inside the container

Kleisli and Co-Kleisli categories

- ▶ Kleisli category of a monad (T, η, μ) on a category \mathcal{C} :
 - ▶ objects of the Kleisli category are the objects of \mathcal{C}
 - ▶ morphisms $f : A \rightarrow B$ of the Kleisli category are the morphisms $f : A \rightarrow TB$ of \mathcal{C}
 - ▶ compositions gf in the Kleisli category correspond to morphisms $\mu(Tg)f$ in \mathcal{C}
 - ▶ identities in the Kleisli category correspond to η in \mathcal{C}
- ▶ Kleisli category intuition:
 - morphisms are effectful computations that also have an input
- ▶ Co-Kleisli categories are the duals of Kleisli categories
